57

58 **Abstract**

59 **BACKGROUND:**

60 The paradoxical association of obesity with mortality, named the “obesity paradox”, has been
61 inconsistent, possibly due to a difference between body mass index (BMI) and central obesity,
62 estimated by waist circumference (WC) as patterns of adiposity.

63
64 **SUBJECTS/METHODS:**

65 We enrolled 8 513 participants from the Kumamoto Intervention Conference Study, a multicenter
66 registry that included consecutive patients undergoing percutaneous coronary intervention (PCI) at 18
67 centers between 2008 and 2017 in Japan. Patients were divided into quartiles in ascending order of the
68 BMI or WC. The primary endpoints were all-cause mortality and cardiovascular death within a year.

69
70 **RESULTS:**

71 There were 186 deaths (case fatality rate, 22.1/1000 person-years) during the follow-up period. The
72 lowest group (1st quartile) of BMI or WC had the worst prognosis among the quartiles (1st quartile,
73 4.2%; 2nd quartile, 1.9%; 3rd quartile, 1.5%; 4th quartile, 1.1%; $P < 0.001$ (χ^2) and 1st quartile, 4.1%;
74 2nd quartile, 2.3%; 3rd quartile, 1.2%; 4th quartile, 1.5%; $P < 0.001$ (χ^2), respectively). Similar results
75 were obtained for cardiovascular death. In a multivariable analysis adjusted by nine conventional
76 factors, the lowest group (1st quartile) of BMI (hazards ratio, 2.748; 95% confidence interval [CI],
77 1.712-4.411) and WC (hazards ratio, 2.340; 95% CI, 1.525-3.589) were independent prognostic factors
78 for all-cause mortality. By dividing the participants into two groups according to either the BMI or
79 WC based on the National Cholesterol Education Program Adult Treatment Panel III and World Health
80 Organization classification, the highest mortality was observed in the lower group. However, the C-
81 statistic after adding BMI (quartile) to conventional factors was found to be slightly higher than BMI
82 (two categories) and WC (two categories) (0.735 vs. 0.734).

83
84 **CONCLUSIONS:**

85 The obesity paradox was observed in patients after PCI, and single-use of BMI (or WC) was
86 sufficient to predict the prognosis of patients after PCI.

87

Introduction

88

Obesity is a growing public health problem, and its prevalence is increasing worldwide [1].

89

In Asian countries, as well as Western countries, obesity has increased over the last few decades as a

90

result of the Westernization of lifestyles [2]. Obesity is associated with cardiovascular risk in the

91

general population, whether defined by body mass index (BMI) or waist circumference (WC) [3,4].

92

However, a counterintuitive association between obesity and mortality, termed the “obesity paradox”,

93

was reported previously [5]. Although the protective effects of obesity have been reported in coronary

94

artery disease (CAD) patients, evidence for an obesity paradox in past studies has been less consistent.

95

BMI is a popular measure of body fat, and most previous studies have focused on BMI to investigate

96

the “obesity paradox”. However, WC may more accurately reflect visceral adiposity than BMI [6],

97

and a previous study thus supported the use of WC in addition to BMI in assessing the risk of death

98

[7].

99

We hypothesized that the inconsistency of the “obesity paradox” may be due, in part, to a

100

difference between BMI and central obesity, estimated by WC, as patterns of adiposity. Thus, we

101

aimed to investigate the additive impact of WC on BMI on clinical outcome in CAD patients.

Materials/Subjects and Methods

103 *Study population*

104 This was a multicenter observational cohort study. Details of the Kumamoto Intervention Conference
105 Study registry have been previously described [8]. From August 2008 to March 2017, 18 495
106 consecutive participants were enrolled, and the exclusion criteria were as follows: (1) no data on the
107 BMI or WC (n = 9452) and (2) unidentified prognosis within a 1-year follow-up (n = 530). We enrolled
108 8 513 participants with complete WC and BMI data to examine the impact of obesity. Each
109 institutional ethics committee approved the study, and informed consent was obtained from all
110 participants. This study complied with the Declaration of Helsinki.

112 *Clinical parameters*

113 Height, body weight, and WC were measured at the initial referral. WC was measured at the midpoint
114 between the lowest rib and the iliac crest. Patients were divided into quartiles in ascending order of
115 the BMI or WC. Other clinical parameters have been previously described [8]. In brief, diabetes was
116 defined as any fasting plasma glucose concentration of ≥ 126 mg/dL or a plasma glucose concentration
117 of ≥ 200 mg/dL after 2 h from the oral glucose tolerance test or diabetes treatment. The definition of
118 hypertension was a blood pressure of $\geq 140/90$ mmHg or hypertension treatment. Dyslipidemia was
119 defined as low-density lipoprotein of ≥ 140 mg/dL (≥ 3.63 mmol/L), high-density lipoprotein < 40

120 mg/dL (<1.04 mmol/L), triglycerides ≥ 150 mg/dL (≥ 1.7 mmol/L), or the use of lipid-lowering therapy.
121 The smoking history was determined through an interview. Chronic kidney disease (CKD) was defined
122 as an estimated glomerular filtration rate of < 60 mL/min per 1.73 m². Peripheral arterial disease was
123 defined as an ankle-brachial index value of < 0.9 in either leg or a history of the treatment of peripheral
124 vascular disease. Acute coronary syndrome (ACS) was defined as ST-segment elevation myocardial
125 infarction, non-ST-segment elevation myocardial infarction, or unstable angina pectoris.

126

127 ***Clinical endpoints***

128 The primary endpoints were 1) all-cause mortality and 2) cardiovascular death within 1 year; it is
129 reported that patients at risk of atherothrombosis may have cardiac events within a year [9]. After the
130 interventional procedure, each institution prospectively followed up with the patients, and events were
131 reported based on medical records and confirmed by direct contact with the patients and/or their
132 families. Cardiovascular death was defined as death due to myocardial infarction, congestive heart
133 failure, or documented sudden cardiac death.

134

135 ***Statistical analysis***

136 Continuous variables with a normal distribution are expressed as the mean \pm standard deviation, and
137 categorical data are presented as numbers (proportions). Fisher's exact test and the chi-square test

138 were used to test differences between the four groups for categorical variables. Analysis of variance
139 was used to analyze the differences in continuous variables between the four groups. The Kaplan–
140 Meier method and log-rank test were used to estimate the event probabilities at 365 days and compare
141 survival times, respectively. Hazard ratios (HRs) and 95% confidence intervals (CIs) for the clinical
142 outcome were calculated using Cox proportional hazards analysis, forced inclusion methods were used
143 for multivariable analyses, and conventional risk factors such as age, sex, diabetes, current smoking,
144 CKD, peripheral arterial disease, old myocardial infarction, ACS, and heart failure (nine prognostic
145 factors) were the variables used. The incremental effects of adding BMI or WC to the prognostic
146 factors were evaluated using continuous net reclassification improvement (NRI) and integrated
147 discrimination improvement (IDI) [10]. A C-statistic of > 0.7 was considered an acceptable
148 discriminatory power, > 0.8 excellent, and > 0.9 outstanding. The improvement in the C-statistic for a
149 model containing a new marker is defined simply; however, this increase is often very small in
150 magnitude. Therefore, improvements in the C-statistic, IDI, and NRI were evaluated in the present
151 study. C-statistics were calculated using the pROC package in R. NRI and IDI were computed using
152 the PredictABEL package. A P-value of < 0.05 was considered to denote statistical significance. All
153 statistical tests were two-sided. Statistical analyses were performed using IBM SPSS Statistics for
154 Mac, Version 26 (IBM Corp., Armonk, NY, USA) and R, version 2.7.0 (Toukei Kagaku Kenkyujo Co.
155 Ltd., Japan).

Results

Clinical characteristics

A total of 8 513 patients who underwent PCI were enrolled in the present study (Figure 1). The median age of the patients was 71.0 (interquartile range: 63.0-78.0) years, and 27% were females. The distributions of the BMI and WC of the patients are shown in Figure 2. The median BMI was 23.9 [21.8-26.1] kg/m² (Figure 2A), and the median WC was 87.0 [82.0-93.0] cm for males and 85.0 [77.5-92.9] cm for females (Figure 2B). The baseline characteristics of the cohort stratified by the BMI and WC are summarized in Tables 1A and 1B, respectively. The BMI and WC cohorts shared similar clinical findings, and in both cohorts, the lowest group (1st quartile) was associated with a higher age; lower proportions of diabetes, hypertension, dyslipidemia, current smoking, previous myocardial infarction, and prior PCI; and higher rates of CKD (including the need for hemodialysis) and ACS.

Primary endpoints at the follow-up

Overall, 186 deaths were recorded during the follow-up period, and the case fatality rate was 22.1/1000 person-years. The causes of death among the four groups are shown in Table 2. The lowest group (1st quartile) of BMI had the highest mortality (4.2%) compared with the other three categories (Figure 3A, upper left; 2nd quartile, 1.9%; 3rd quartile, 1.5%; or 4th quartile, 1.1%) ($P < 0.001$ (χ^2)). The lowest

174 group (1st quartile) of BMI also had the highest rate of cardiovascular death (1.3%) (Figure 3A, upper
175 right; 2nd quartile, 0.7%; 3rd quartile, 0.6%; or 4th quartile, 0.5%) ($P = 0.016$ (χ^2)). We performed
176 Kaplan–Meier analysis and observed that there was a significant difference in all-cause mortality
177 among the four categories (Figure 3A, lower left; log-rank $P < 0.001$). The difference was also
178 statistically significant for cardiovascular death (Figure 3A, lower right; log-rank $P = 0.015$). Similar
179 results were obtained for WC; however, the relationship between mortality, cardiovascular death, and
180 WC appeared to be reverse J-shaped; the mortality rate was the lowest in the 3rd quartile (Figure 3B).
181 Moreover, we examined all-cause mortality (Supplemental Figures 1A and 1C) and cardiovascular
182 death (Supplemental Figures 1B and 1D) within 1-month and from 1-month to 1-year. In terms of the
183 BMI and WC, the lowest group was significantly associated with all-cause mortality and
184 cardiovascular death from 1-month to 1-year (Supplemental Figures 2A to 2D).

185

186 *Cox proportional hazards analysis*

187 The results of the univariable and multivariable Cox proportional hazards analyses for all-cause
188 mortality are summarized in Table 3. In the multivariable analysis adjusted by nine prognostic factors,
189 the lowest group (1st quartile) of BMI and WC were independently associated with 1-year mortality
190 (Table 3; HR, 2.748; 95% CI, 1.712-4.411; $P < 0.001$ and HR, 2.340; 95% CI, 1.525-3.589; $P < 0.001$,
191 respectively). Even after including BMI and WC as continuous variables, BMI (HR, 0.851; 95% CI,

192 0.811-0.893; $P < 0.001$) and WC (HR, 0.956; 95% CI, 0.941-0.971; $P < 0.001$) were independent
193 prognostic factors for all-cause mortality. Neither the BMI nor the WC quartiles were associated with
194 cardiovascular death in the multivariable analyses (data not shown).

195

196 ***C-statistic for regression models, continuous NRI, and IDI***

197 C-statistic values were calculated for all-cause mortality within the 1-year follow-up. The C-statistic
198 of the variables, including nine prognostic factors, was 0.719 (95% CI, 0.680-0.758) vs. 0.735 (95%
199 CI, 0.696-0.774) after including the BMI quartile; the continuous NRI and IDI were 0.294 (0.151-
200 0.438; $P < 0.001$) and 0.0055 (0.0003-0.0078; $P < 0.001$), respectively (Table 4). The C-statistic
201 increased from 0.735 to 0.739 by adding the WC quartile to these factors; the continuous NRI and
202 IDI were 0.358 (0.218-0.499; $P < 0.001$) and 0.001 (-0.001-0.0022; $P = 0.076$), respectively (Table
203 4). The receiver operating characteristic curve is shown in Supplemental Figure 2.

204

205 ***BMI/WC in two categories divided by National Cholesterol Education Program Adult Treatment***

206 ***Panel III and World Health Organization classification***

207 Patients were supplementarily divided by the modified National Cholesterol Education Program Adult
208 Treatment Panel III criteria with ethnic-specific values and the World Health Organization
209 classification for the general definition of obesity. Patients with a BMI of ≥ 25 kg/m² were defined as

210 having an obese BMI, and those with a WC of ≥ 85 cm for men or ≥ 90 cm for women were defined
211 as having an obese WC.

212 The clinical parameters of the two groups are shown in Supplemental Tables 1A and 1B. Similar to
213 previous results (Tables 1A and 1B), the higher group was associated with younger age; higher
214 proportions of males and participants with diabetes, hypertension, dyslipidemia, current smoking, and
215 prior PCI; and lower rates of CKD (including the need for hemodialysis) and ACS.

216 We performed a Kaplan–Meier analysis among the two categories of BMI or WC, and as a result, non-
217 obese BMI and non-obese WC showed the highest mortality (Supplemental Figures 3A and 3B upper
218 left; 2.6% vs. 1.4%; $P < 0.001$ and 3.0% vs. 1.4%; $P < 0.001$, respectively).

219 The C-statistic of the nine prognostic factors + the BMI value was 0.724 (95% CI, 0.685-0.764) and
220 continuous NRI and IDI were 0.277 (0.154-0.400; $P < 0.001$) and 0.0013 (0.0003-0.0023; $P = 0.010$),
221 respectively (Supplemental Table 2). The C-statistic increased from 0.724 to 0.734 by adding the WC
222 value to these factors; the continuous NRI and IDI were 0.402 (0.265-0.539; $P < 0.001$) and 0.0028
223 (0.001-0.0047; $P = 0.002$), respectively (Supplemental Table 2).

224

225

Discussion

226 The main findings of this study were as follows: (1) the lowest BMI or WC groups were associated
227 with worse outcomes, and 1st quartiles of BMI and WC were independent prognostic factors of all-
228 cause mortality by the multivariable analyses; (2) significant predictive model improvements by
229 significant NRI were observed after adding the BMI and then the WC quartiles to the model of
230 conventional factors; (3) significant IDI was also observed after adding the BMI quartile to the
231 model of conventional factors but not after adding the WC quartile to the model of conventional
232 factors and the BMI quartile; (4) similar results were obtained by dividing the participants into two
233 groups according to BMI or WC by the National Cholesterol Education Program Adult Treatment
234 Panel III criteria and the World Health Organization classification, and the highest mortality was
235 observed in the lower group; (5) the C-statistic after adding BMI (quartile) to the conventional
236 factors was found to be slightly better than the BMI (two categories) and WC (two categories)
237 (0.735 vs. 0.734).

238

239

240 *Effect of BMI and WC in the obesity paradox*

241 BMI is the most popular criterion of obesity and is associated with total body fat [11,12], and there
242 have been many reports of the “obesity paradox” using the BMI of patients with coronary artery

243 disease (CAD) [13]. However, BMI is just a surrogate measure of body fat, and the validity of the
244 “obesity paradox” using BMI has been called into question [14] because BMI does not distinguish
245 between lean and fat mass. Abdominal obesity has been reported to be significantly different in any
246 BMI category [15]. Gaining lean body mass is generally a "health index" and predictor of better
247 outcomes in humans without cardiovascular disease.

248 WC, which is the perimeter of the abdomen, is an alternative index of obesity that may be more
249 specific for visceral fat. A paradoxical link between obesity defined by WC and favorable prognosis
250 has also been demonstrated in patients with heart failure [16, 17] and atrial fibrillation [18].

251 Furthermore, Ono et al. enrolled 1 799 patients with left main CAD or three-vessel disease and
252 reported that body composition should be assessed by BMI and WC in the appropriate evaluation of
253 the long-term risk of obesity [19].

254 The present study included 8 513 patients, and we believe this is the largest study to verify the
255 “obesity paradox” in patients with CAD requiring PCI using the BMI or WC, and our results suggest
256 that higher WC is correlated with better outcomes in patients with CAD. As previously reported, this
257 study showed that the “obesity paradox” in patients with CAD could apply to the WC. Although WC
258 is a better indicator of central obesity, it is still a proxy of obesity, and as such, it can also be
259 subjected to biases since it appears that the relative proportion of lean vs. fat mass appears to be the
260 causative factor behind this “paradoxical protective effect of obesity.”

261 In contrast to previous work, in the present study, the participants were divided into quartiles
262 according to their BMI and WC, and it was found that patients in the lowest group of BMI and WC
263 had the worst prognosis following PCI. It can be stated that this study confirms that other
264 anthropometric indices such as the WC provide evidence supporting the idea that after acute and
265 chronic atherothrombotic and cardiovascular diseases, it appears that some body mass is necessary
266 to face the challenges of survival. However, mortality and cardiovascular death were linear in terms
267 of the BMI but reverse J-shaped in terms of the WC. This indicates that excessive visceral fat might
268 increase mortality, suggesting that the paradoxical effect of obesity is not incremental.

269 Moreover, it was found that adding the BMI quartile improved prognosis prediction with significant
270 NRI and IDI; however, after adding the WC quartile, the increase in C-statistics was very small
271 (from 0.735 to 0.739), and its IDI was not significant ($P = 0.076$) (Table 4). In addition, the C-
272 statistic of the nine prognostic factors + BMI (two categories) + WC (two categories) was 0.734,
273 whereas the C-statistic of the nine prognostic factors + BMI (quartile) was 0.735 (Table 4 and
274 Supplemental Table 2). This indicates that the addition of BMI (quartile) is only slightly better than
275 the addition of BMI (two categories) and WC (two categories) for prognosis prediction after PCI.

276 Therefore, for prognosis prediction after PCI, measurement of BMI or WC may be sufficient
277 (measurements of both BMI and WC are not always necessary).

278

279 *Possible explanations for the protective effect of obesity*

280 Several reports have addressed the mechanisms of the “obesity paradox:” (1) plasma lipoproteins
281 decrease inflammatory cytokines [20]; (2) people with obesity have more energy than people
282 without obesity to move their bodies due to their increased weight, and myocardial ischemic
283 symptoms tend to occur earlier [21]; (3) antithrombotic and/or antiplatelet drugs increase the risk of
284 adverse events at extremely low body weights, resulting in increased bleeding events in the non-
285 obesity group [22]; (4) anatomical differences might contribute to the benefit of people with obesity,
286 as petite patients usually have smaller coronary arteries and might suffer from an increased risk of
287 stent thrombosis after PCI [23]. Therefore, lean body mass might explain why people without
288 obesity have increased mortality and why overweight patients have better outcomes [24]. In contrast
289 to visceral (abdominal) fat, abdominal subcutaneous fat accumulation results in beneficial systemic
290 metabolism and cardiovascular protective effects [25].

291 In the present study, we additionally investigated all-cause mortality and cardiovascular death within
292 1 month and from 1 month to 1 year. We found that the difference in the survival rate among the four
293 groups became clear after 1 month (Supplemental Figure 1). Therefore, it could be said that obesity
294 is involved in long-term survival, and is not a problem during the PCI perioperative period. It is
295 possible that advances in PCI devices and techniques have brought about this result, and the number
296 of cardiovascular deaths reported in the present study in 1-year were as few as 64.

297 The underweight group had a higher rate of cardiovascular death (Figure 3); however, many non-
298 cardiovascular events also caused death. One possible explanation is that people without obesity
299 may be frail and cachexic and may suffer from non-cardiac diseases such as cancer, sepsis, and
300 hemorrhagic events. In fact, when we investigated the cause of death, we found that the lowest group
301 tended to die from various causes such as sepsis, bleeding, cancer, and multiple organ failure (Table
302 2). For such patients, a reduction to 2.5 mg may be considered for low doses of prasugrel to reduce
303 bleeding events.

304

305 ***Study limitations***

306 The present study has several limitations. First, we enrolled only Japanese patients, and our results
307 may not be generalizable worldwide. Second, 9 982 patients (54%) were excluded from the study
308 due to the lack of BMI, WC, and follow-up data within 1 year. Comparing the excluded and
309 analyzed cohorts, there were significant differences in sex; age; weight; height; BMI; WC;
310 hypertension; dyslipidemia; smoking; CKD; old myocardial infarction; ACS; and the rate of use of
311 aspirin, clopidogrel, cilostazol, ticlopidine, and sarpogrelate. Therefore, selection bias may have
312 occurred. Third, WC and BMI were assessed at one point; however, the degree of obesity and loss of
313 muscle mass may represent the progression of chronic disease. In addition, the lowest BMI or WC
314 group may include poorly nourished patients and those with cancer history; however, the present

315 study is based on a multicenter registry, and the present data lacked nutritional indicators (such as
316 albumin and lymphocyte counts) and cancer details. Moreover, we did not directly quantify or
317 measure fat mass, such as with dual-energy X-ray absorptiometry or computed tomography. In
318 addition, there were no data on cytokines or adipokines. In addition, WC is one of the most difficult
319 anthropometric measures in terms of consistency between evaluators, and since this is a multicenter
320 study, we cannot discard the possibility that variations in measurements across institutions might
321 introduce some bias into the statistical analyses. In addition, the fact that neither BMI quartile nor
322 WC quartile was associated with cardiovascular death in the multivariable analyses suggests that
323 there may be some biases in this dataset.

324

325 ***Conclusion***

326 The obesity paradox was observed in patients after PCI, and single-use of BMI (or WC) was sufficient
327 to predict the prognosis of patients after PCI, lending further support to the paradoxical effect of
328 obesity.

424

425 **Figure 1. Study flow chart.**

426 From August 2008 to March 2017, 18 495 consecutive participants were recorded in this registry,
427 and we excluded patients without the BMI or WC data and those with unidentified prognoses during
428 the 1-year follow-up. As a result, 8 513 patients who underwent PCI were included in this study.

429 Patients were divided into quartiles in ascending order of the BMI or WC.

430 BMI, body mass index; WC, waist circumference; PCI, percutaneous coronary intervention

431

432 **Figure 2. Histogram of BMI (A) and WC (B) in all patients.**

433 The median BMI was 23.9 [21.8-26.1] kg/m², and the median WC was 87.0 [82.0-93.0] cm for
434 males and 85.0 [77.5-92.9] cm for females.

435 BMI, body mass index; WC, waist circumference

436

437 **Figure 3. Event rates among the four groups according to the BMI (A) and WC (B) in the** 438 **quartile.**

439 The survival rate was examined using the BMI and WC in the quartile, respectively. The lowest group
440 (1st quartile) of BMI had the highest mortality (4.2%) compared with the three other categories (Figure
441 3A, upper left; 2nd quartile, 1.9%; 3rd quartile, 1.5%; or 4th quartile, 1.1%) ($P < 0.001(\chi^2)$). The lowest

442 group (1st quartile) of BMI also had the highest rate of cardiovascular death (1.3%) (Figure 3A, upper
443 right; 2nd quartile, 0.7%; 3rd quartile, 0.6%; or 4th quartile, 0.5%) ($P = 0.016(\chi^2)$). We performed
444 Kaplan–Meier analysis and observed that there was a significant difference in all-cause mortality
445 among the four categories (Figure 3A, lower left; log-rank $P < 0.001$). The difference was also
446 statistically significant for cardiovascular death (Figure 3A, lower right; log-rank $P = 0.015$). Similar
447 results were obtained for WC (Figure 3B).

448 BMI, body mass index; WC, waist circumference

449

Table 1A. Baseline Characteristics Stratified by Body Mass Index in Quartile

Adjusted by age, sex, chronic kidney disease, acute coronary syndrome, old myocardial infarction, diabetes, current smoking, heart failure, and peripheral arterial disease. Abbreviations: HR, hazard ratio; CI, confidence interval; BMI, body mass index; WC, waist circumference; CKD, chronic kidney disease; ACS, acute coronary syndrome; OMI, old myocardial infarction; DM, diabetes; HF, heart failure; PAD, peripheral arterial disease; ACS, acute coronary syndrome;

Table 4. NRI and IDI by adding quartiles of BMI and WC to 9 prognostic factors

Variable	C-statistics	NRI	<i>P</i> value	IDI	<i>P</i> value
Factor 9	0.719				
Factor 9 + BMI (quartile)	0.735	0.294 (0.151-0.438)	< 0.001	0.0055 (0.0003-0.0078)	<0.001
Factor 9 + BMI + WC (quartile)	0.739	0.358 (0.218-0.499)	< 0.001	0.001 (-0.001-0.0022)	0.076

Abbreviations: Factor 9 (age, sex, chronic kidney disease, acute coronary syndrome, old myocardial infarction, diabetes, current smoking, heart failure, and peripheral arterial disease); NRI, net reclassification improvement; IDI, integrated discrimination improvement; BMI, body mass index; WC, waist circumference

Supplemental table 1A. Baseline Characteristics Stratified by Body Mass Index-defined obesity

	Non-Obesity (Low BMI: n=5424)	Obesity (High BMI: n=3089)	<i>P</i> value
Age in years (median range)	73.0 (65.0 – 80.0)	68.0 (60.0 – 75.0)	<0.001
Female, n (%)	1519 (28.0)	734 (23.8)	<0.001
Height (cm)	159.4±9.3	161.1±9.4	<0.001
Weight (kg)	56.5±9.0	72.1±10.7	<0.001
BMI (kg/m ²)	22.1±2.1	27.7±2.6	<0.001
Waist Circumference (cm)	82.5±7.6	94.6±8.3	<0.001
eGFR mL/min/1.73 m ²	60.8±23.4	64.1±23.4	<0.001
HbA1c (%)	6.3±1.1	6.6±2.3	<0.001
Diabetes, n (%)	2082 (38.4)	1487 (48.2)	<0.001
Hypertension, n (%)	4183 (77.3)	2570 (83.3)	<0.001
Dyslipidaemia, n (%)	3295 (60.8)	2227 (72.2)	<0.001
Smoking, n (%)	1111 (20.5)	760 (24.7)	<0.001
CKD, n (%)	2415 (44.7)	1232 (40.0)	<0.001
On HD, n (%)	308 (5.7)	104 (3.4)	<0.001
Prior MI, n (%)	947 (17.5)	591 (19.2)	0.057
Prior PCI, n (%)	1364 (25.2)	851 (27.6)	0.016
Prior CABG, n (%)	230 (4.2)	133 (4.3)	0.911
Composite of PAD, n (%)	481 (8.9)	205 (6.6)	<0.001
ACS, n (%)	2410 (44.4)	1287 (41.7)	0.013
DES, n (%)	4060 (74.9)	2319 (75.1)	0.835
Anti thrombotic agents after PCI			
Aspirin, n (%)	5366 (99.1)	3060 (99.2)	0.811
Clopidogrel, n (%)	3891 (72.0)	2183 (70.9)	0.317
Prasugrel, n (%)	708 (37.0)	414 (38.1)	0.556
Cilostazol, n (%)	129 (2.4)	66 (2.1)	0.498
Ticlopidine, n (%)	702 (13.0)	429 (13.9)	0.219
Sarpogrelate, n (%)	40 (0.7)	23 (0.7)	1.000
DOAC, n (%)	138 (7.8)	73 (6.8)	0.604
Warfarin, n (%)	414 (7.6)	210 (6.8)	0.154

Abbreviations: BMI, body mass index; eGFR, estimated glomerular filtration rate; CKD, chronic kidney disease; HD, haemodialysis; MI, myocardial infarction; PCI, percutaneous coronary intervention; CABG, coronary artery bypass; PAD, peripheral arterial disease; ACS, acute coronary syndrome; DES, drug-eluting stent; BMS, bare metal stent; DOAC, direct oral anticoagulants

Supplemental table 1B. Baseline characteristics stratified by waist circumference-defined obesity

	Non-Obesity (Low WC: n=4180)	Obesity (High WC: n=4333)	<i>P</i> value
Age in years (median range)	73.0 (65.0 – 80.0)	69.0 (61.0 – 76.0)	<0.001
Female, n (%)	1606 (38.4)	647 (14.9)	<0.001
Height (cm)	157.0±9.3	163.0±8.4	<0.001
Weight (kg)	54.5±8.7	69.5±10.4	<0.001
BMI (kg/m ²)	22.1±2.6	26.1±3.1	<0.001
Waist Circumference (cm)	79.4±6.0	94.2±6.8	<0.001
eGFR mL/min/1.73 m ²	60.8±24.0	63.2±22.9	<0.001
HbA1c (%)	6.3±1.1	6.6±2.0	<0.001
Diabetes, n (%)	1538 (36.8)	2031 (47.0)	<0.001
Hypertension, n (%)	3215 (77.0)	3538 (81.8)	<0.001
Dyslipidaemia, n (%)	2485 (59.5)	3037 (70.2)	<0.001
Smoking, n (%)	757 (18.2)	1114 (25.8)	<0.001
CKD, n (%)	1872 (45.0)	1775 (41.1)	<0.001
On HD, n (%)	250 (6.0)	162 (3.7)	<0.001
Prior MI, n (%)	672 (16.1)	866 (20.0)	<0.001
Prior PCI, n (%)	955 (23.8)	1220 (28.2)	<0.001
Prior CABG, n (%)	194 (4.6)	169 (3.9)	0.096
Composite of PAD, n (%)	346 (8.3)	340 (7.9)	0.473
ACS, n (%)	1887 (44.9)	1820 (42.0)	0.007
DES, n (%)	3135 (75.0)	3244 (74.9)	0.900
Anti thrombotic agents after PCI			
Asprin, n (%)	4131 (99.0)	4295 (99.2)	0.206
Clopidogrel, n (%)	3020 (72.5)	3054 (70.7)	0.067
Prasugrel, n (%)	516 (37.2)	606 (37.6)	0.820
Cilostazol, n (%)	92 (2.2)	103 (2.4)	0.612
Ticlopidine, n (%)	550 (13.2)	581 (13.4)	0.749
Sarpogrelate, n (%)	29 (0.7)	34 (0.8)	0.705
DOAC, n (%)	99 (7.2)	112 (7.1)	0.886
Wafarin, n (%)	309 (7.4)	315 (7.3)	0.835

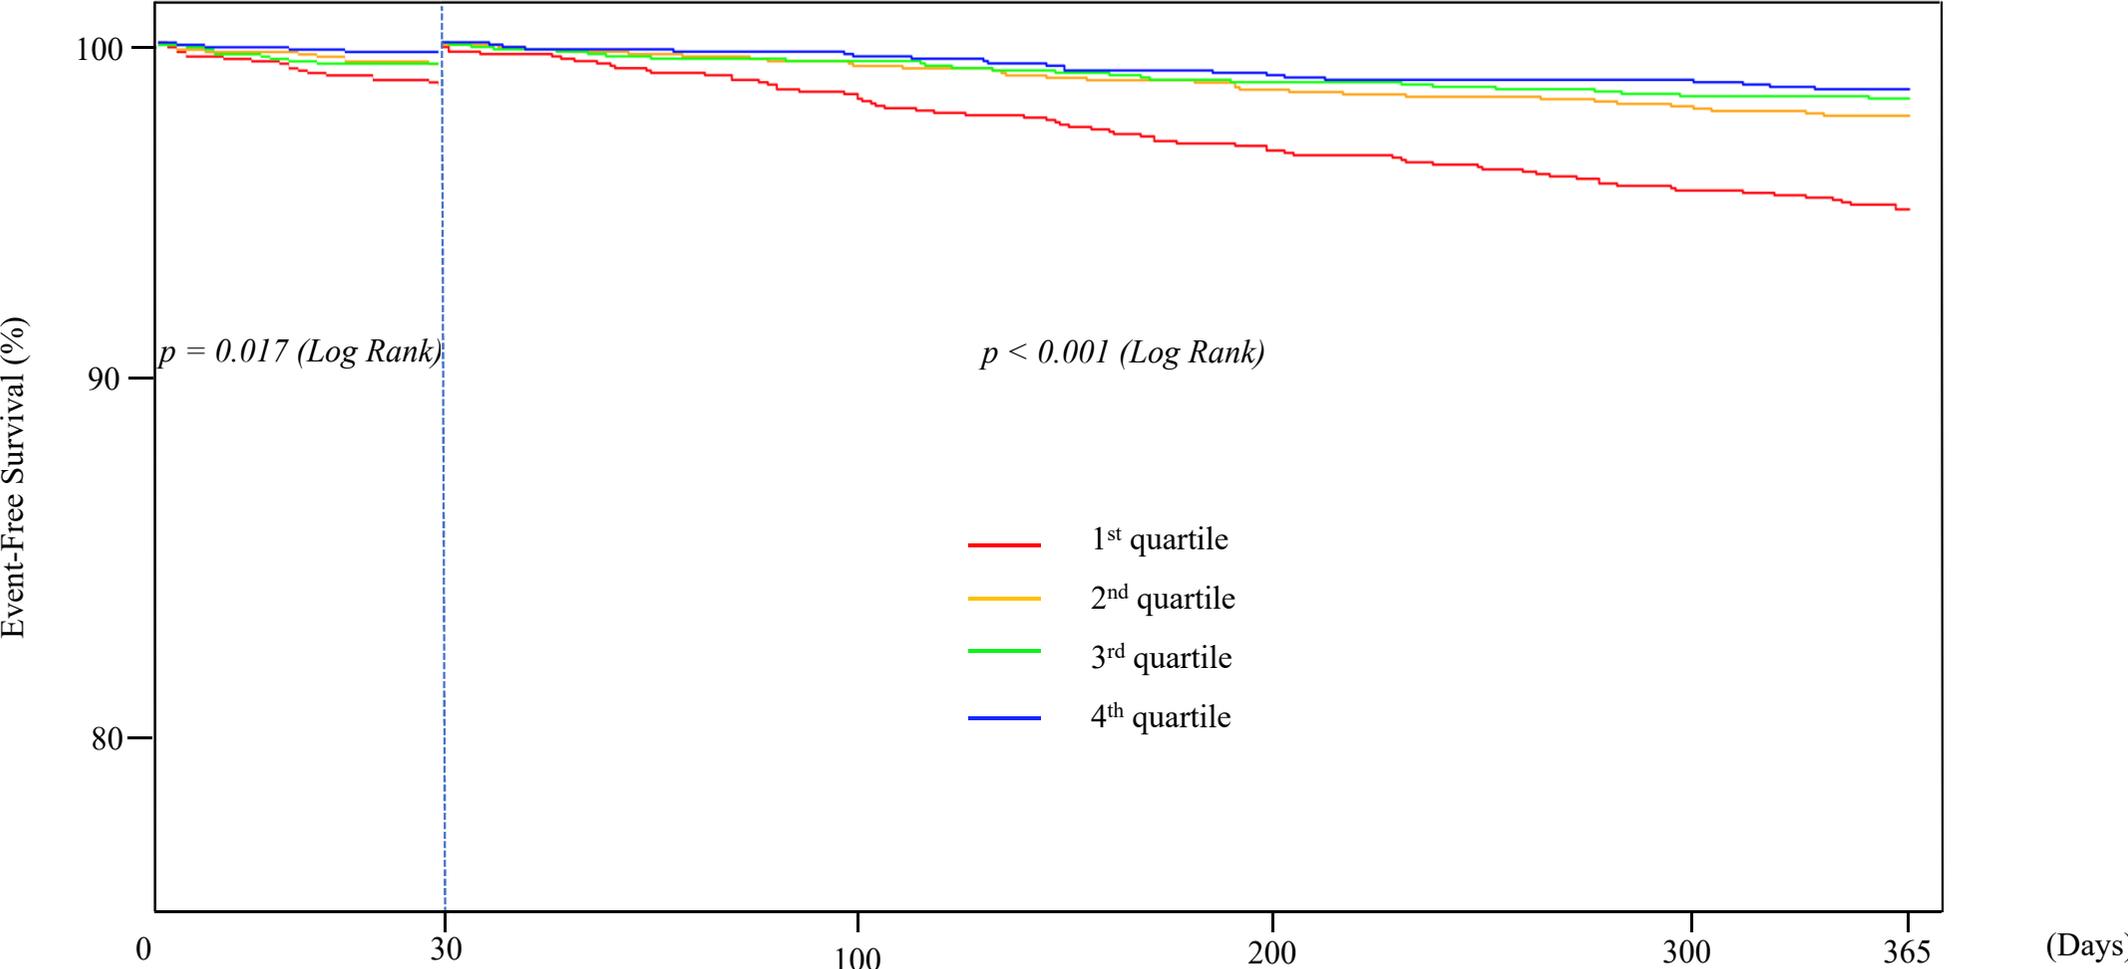

Abbreviations: BMI, body mass index; eGFR, estimated glomerular filtration rate; CKD, chronic kidney disease; HD, haemodialysis; MI, myocardial infarction; PCI, percutaneous coronary intervention; CABG, coronary artery bypass; PAD, peripheral arterial disease; ACS, acute coronary syndrome; DES, drug-eluting stent; BMS, bare metal stent; DOAC, direct oral anticoagulants

Supplemental table 2. NRI and IDI by adding BMI and WC to 9 prognostic factors

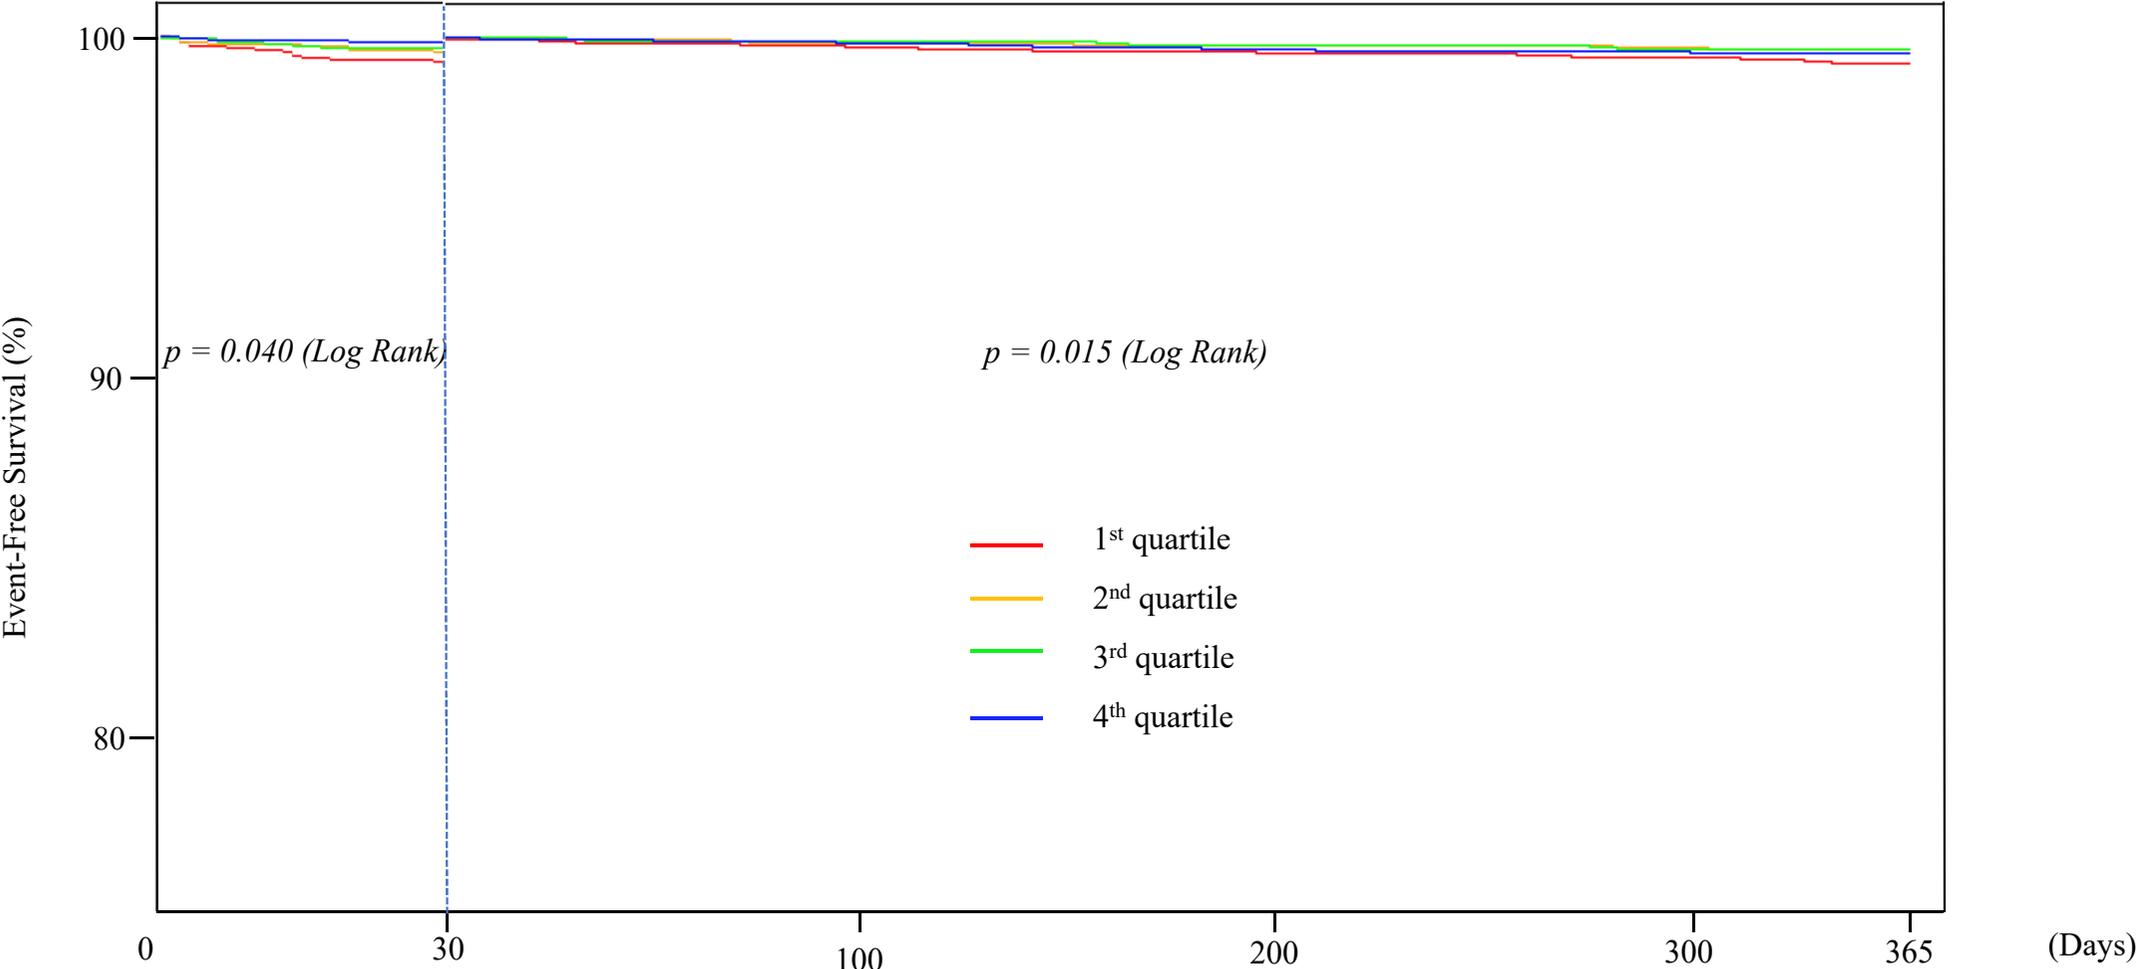

Variable	C-statistics	NRI	<i>P</i> value	IDI	<i>P</i> value
Factor 9	0.719				
Factor 9 + Low BMI	0.724	0.277 (0.154-0.400)	< 0.001	0.0013 (0.0003-0.0023)	0.01
Factor 9 + Low BMI + Low WC	0.734	0.402 (0.265-0.539)	< 0.001	0.0028 (0.001-0.0047)	0.002

Abbreviations: Factor 9 (age, sex, chronic kidney disease, acute coronary syndrome, old myocardial infarction, diabetes, current smoking, heart failure, and peripheral arterial disease); NRI, net reclassification improvement; IDI, integrated discrimination improvement; BMI, body mass index; WC, waist circumference
